The invention relates to an electrically operated valve, comprising a valve housing in which a valve seat is located and in which there is a valve element which is movable by the force of a valve stem that extends into the valve housing, and in which the valve stem comprises a main stem part which extends into the valve housing and which is connected with the valve element at the end remote from the valve seat, and a connecting part which is located in the main stem part and which is connected with the valve element in its immediate vicinity of the valve seat. Such valves are known in various designs, wherein the main stem part of the valve stem is connected with the valve element via the connecting part by means of a screw connection, a press fit or, for example, a weld connection. In valves of this type there is the possibility, in particular in the case of valves which have very small clearances, that the screw connection between the valve stem and the connecting part which is located in the main stem part, or the press fit or the weld connection, will, due to the poor quality of the connection, fail or break. If the connecting part breaks away from the valve stem, the valve may malfunction and, in extreme cases, the valve element may even break off from the main stem part. According to U.S. Pat. No. 3,844,100 a valve of the type mentioned in the opening part of this specification is known. According to this publication the valve element and the connecting part are connected by means of a weld connection. The object of the invention is to provide a valve in which the possibility of a break in the connecting part of the valve stem is largely reduced. This object is achieved according to the invention in that the connecting part has a weld connection with a welded connection zone which is
