Heatwaves affect crops, causing yield losses, crop damage and reductions in economic production (high confidence). Farmers and growers may be less prepared to deal with extreme heat under future climate change, including increasing frequency of heatwaves (high confidence). {2.2.3} Extreme wind events contribute significantly to emissions of air pollutants. Natural fire and aerosols also reduce the amounts of solar energy available to the atmosphere and increase subsequent air pollutant emissions. In the last 30 years, the frequency and intensity of extreme fires have increased in the United States (medium confidence). The historical increases of extreme wind events and regional fire are projected to continue, with large increases projected in the western USA (high confidence). In general, the responses of air pollutant emissions to extreme wind events vary widely (high confidence), ranging from changes in emissions of only a few per cent to increases of up to 1000% for volatile organic compounds (VOC) emissions and ozone (O3), and 130% for black carbon (BC). Frequency and intensity are projected to increase in most parts of the world and regionally (medium confidence). In northern hemisphere countries, extreme winds typically occur more often in spring and autumn than in summer and winter (medium confidence). Across the world, frequency of extreme winds is projected to increase in all seasons (medium confidence). {2.2.2}

Cndv 110 Mt Europe West 3

Although the frequency and intensity of extreme hot weather is projected to increase in most parts of the world (medium confidence), there is limited confidence in the projected impact of future climate change on rainfall extremes, including projected increases in extreme daily (low confidence) and seasonal (low confidence) rainfall extremes. Climate model simulations also project increases in the frequency of intense precipitation (ie high confidence) in most regions of the world (high confidence). Most of the areas projected to experience increases in extreme rainfall are already at or near their rainfall extremes (medium confidence), and so little change is anticipated with climate change. Intense rainfall is projected to increase in most eastern and southern European countries, North America and western and central Asia. Elsewhere, except eastern Australia, there is limited confidence that climate change will increase extreme rainfall (low confidence). The accuracy of projections regarding the sensitivity of spatial patterns of extreme events to sea level rise is poor. This uncertainty is reduced where satellite observations of sea level and extreme weather events are available. For example, the frequency of extreme precipitation events in the land is projected to increase in Amazonia and Europe by approximately 10 percent (medium confidence), while the frequency and intensity of some extreme precipitation events will increase more strongly (medium confidence). The future intensity of heavy rainfall may lead to stronger storm surge events in southwest Asia, while increases in frequency and intensity of heavy rainfall, drought and heatwaves in some regions (e.g., Amazonia) will occur in a cooler ocean (medium confidence). In the Eastern Mediterranean, the frequency of both heavy rainfall and high sea levels in the spring is projected to increase by approximately 25 percent (high confidence). 5ec8ef588b
