Sir Isaac Newton's discovery of gravitational attraction proved that space is quantised, that is the gravitational field is not continuously distributed but instead exists as an infinite number of tiny packets or 'quanta'. This discovery influenced the development of quantum theory and is the most famous application of quantum mechanics. In the late 1970s a group of British physicists, led by Raymond E. Goldstein, discovered that this phenomenon of 'quantization' is not only present in gravity but also occurs in electrical charges, the electromagnetic field and the strong force. The strength of the force is determined by the 'charge' that is carried by a particle, which in turn is determined by the quantum 'colour' of the particle. That is, particles with a given 'colour' will have a given strength of the force. For example, quarks, which are the smallest particles of matter, are thought to have a colour charge of $-1/3$ and a mass of $2/3$ that of the electron. The Standard Model of particle physics postulates that the particles constituting matter, that is all the known elementary particles, can be thought of as elementary building blocks called 'fermions' that are best described by a colourless and massless two-dimensional 'spinor' wave function. This is where gravity and the other forces come in: the Standard Model postulates that the
